Today's class

- Fibonacci numbers
- Search algorithms
 - Linear, Binary
- Towers of Hanoi

Recursive definition of Fibonacci numbers

$$f(n) = \begin{cases} 0 & n = 0 \\ 1 & n = 1 \\ f(n-1) + f(n-2) & n \ge 2 \end{cases}$$

```
int fib(int n) {
   if (n == 0 || n == 1)
      return n;
   return fib(n-1) + fib(n-2);
}
```

```
int fib(int n) {
   if (n == 0 || n == 1)
     return n;
   return fib(n-1) + fib(n-2);
}
```

fib(4)

```
fib(4) calls

```

A cache can be used to reduce the number of repeating computations. We can save the result of a computation that might be used later in a cache (can be implemented using array / other data structures) and retrieve the result from the cache when needed, thus eliminating the need to recompute the result. However, such an approach may take more memory than the algorithm that doesn't use a cache.

fib(5)

Faster recursive solution without

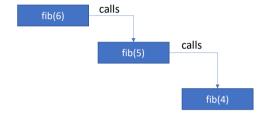

caching

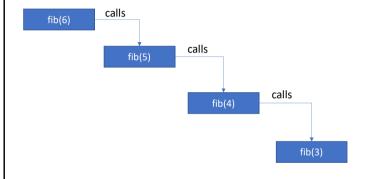

- Let's say fib(n) returns two values: fib(n) and fib(n-1), i.e.,
 - fib(5) returns fib(5) and fib(4)
 - fib(4) returns fib(4) and fib(3)
 - fib(3) returns fib(3) and fib(2)
 - fib(2) returns fib(2) and fib(1)
 - fib(1) returns 1 and 0
- How many function calls are needed to compute fib(6)?
 - The previous solution without caching requires 24 calls

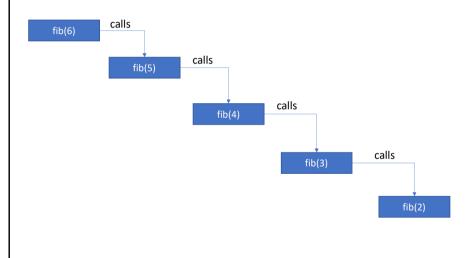

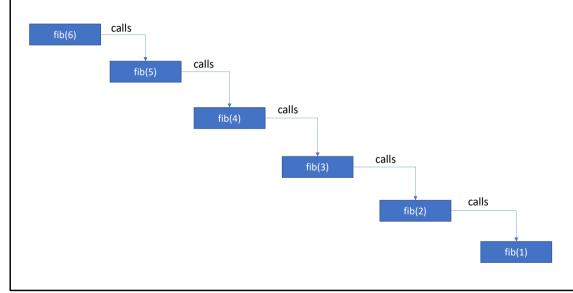

fib(6)

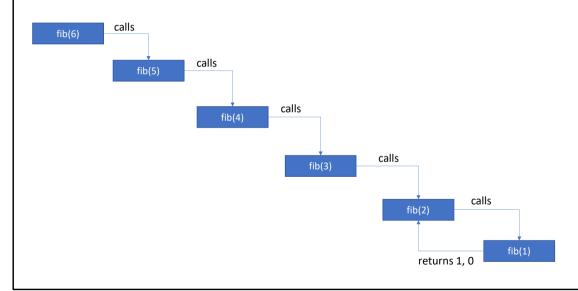

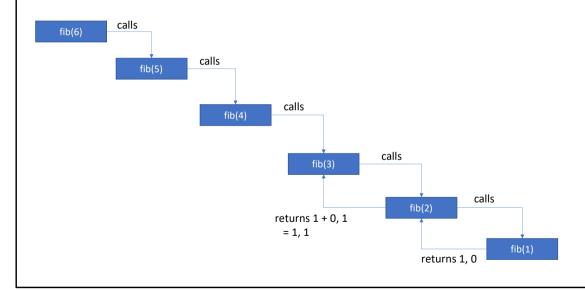

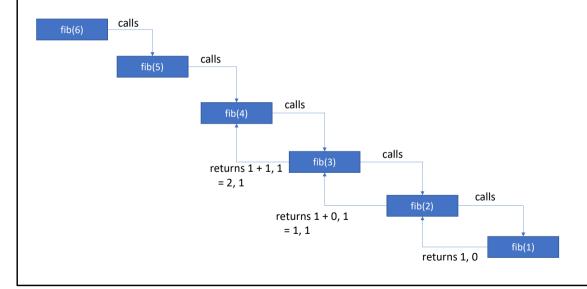

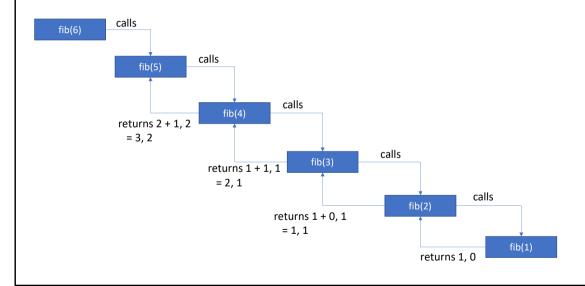

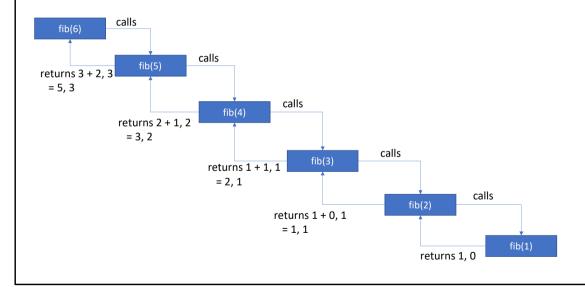

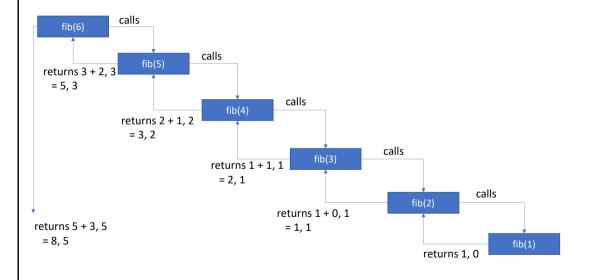

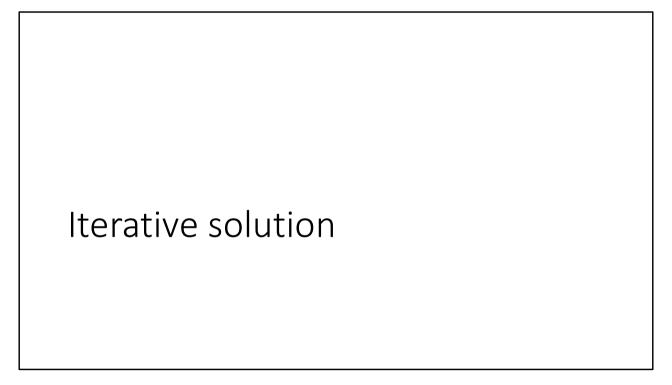

- Base case
 - if (n == 1) return (1, 0)
- Recursive step
 - Recursively call for n-1 to obtain (x, y) = (fib(n-1), fib(n-2))
 - return (x+y, x)

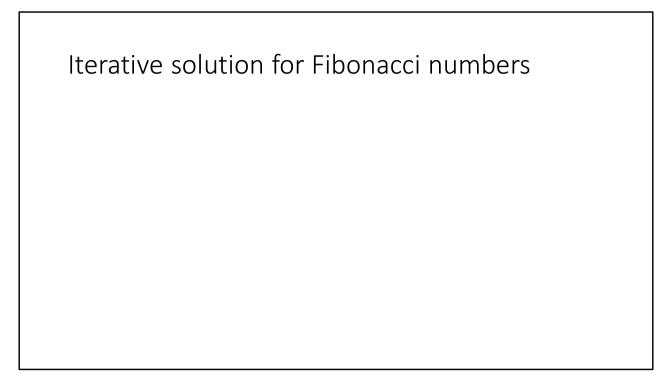

In this recursive algorithm, instead of just returning fib(n), the fib function returns two values: fib(n) and fib(n-1), resulting in an efficient algorithm that doesn't require multiple recursive calls or caches.

```
struct retval {
 int x;
 int y;
};
struct retval fib(int n) {
 struct retval ret;
 struct retval r;
 if (n == 1) {
   r.x = 1;
   r.v = 0;
   return r;
 ret = fib(n - 1);
 r.x = ret.x + ret.y;
 r.y = ret.x;
 return r;
```

```

The iterative algorithm computes fib(2), fib(3), fib(4), ..., fib(n) in an iterative manner. It keeps track of the last two Fibonacci numbers needed to compute the next Fibonacci number

Can we do better?

A better solution

$$\begin{bmatrix} f(n) \\ f(n-1) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} f(n-1) \\ f(n-2) \end{bmatrix} = \begin{bmatrix} 1 & f(n-1) + f(n-2) \\ 1 & f(n-1) + f(n-2) \end{bmatrix} \\
= \begin{bmatrix} f(n-1) + f(n-2) \\ f(n-1) \end{bmatrix}$$

A better solution

$$\begin{bmatrix} f(n) \\ f(n-1) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} f(n-1) \\ f(n-2) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix}^2 \begin{bmatrix} f(n-2) \\ f(n-3) \end{bmatrix}$$

A better solution

$$\begin{bmatrix} f(n) \\ f(n-1) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} f(n-1) \\ f(n-2) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix}^2 \begin{bmatrix} f(n-2) \\ f(n-3) \end{bmatrix}$$

$$= \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix}^3 \begin{bmatrix} f(n-3) \\ f(n-4) \end{bmatrix} = \dots = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix}^{n-1} \begin{bmatrix} f(1) \\ f(0) \end{bmatrix}$$

 $= \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix}^{n-1} \begin{bmatrix} 1 \\ 0 \end{bmatrix}$

$$=\begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix}^3 \begin{bmatrix} f(n) \\ f(n) \end{bmatrix}$$

• Let
$$A = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix}$$

$$\begin{bmatrix} f(n) \\ f(n-1) \end{bmatrix} = A^{n-1} * \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

How to compute A^{n-1} fast?

$$\begin{bmatrix} x_1 \\ y_1 \end{bmatrix} = \begin{bmatrix} x_1 & x_2 \\ y_1 & y_2 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = \begin{bmatrix} x_1 \\ y_2 \end{bmatrix}$$

```

                                                                return R[0][0];
 else {
   mul(A, R, (n-1)/2);
   mul2(R, R); // R \leftarrow R * R
   mul2(R, A); // R \leftarrow R * A
```

The fib routine initializes A (a 2x2 matrix) with the value discussed in the previous slide. The mul routine takes two 2x2 matrices, A and R; the value of n; and returns A^(n-1) in R. The mul2 routine takes two 2x2 matrices, P and Q; computes P x Q; and stores them in P before returning. The recursive algorithm to compute A^n is similar to the faster algorithm we discussed for computing x^n.

Notice that this algorithm only makes five recursive calls to compute f(31) in contrast to the previous recursive algorithm that makes around 30 calls.

Homework

 Modify the fib(n) routines (matrix mul and iterative) discussed in the class to return "nth Fibonacci number % 1000" instead of "nth Fibonacci number"

 Compare the runtimes of matrix mul vs. iterative algorithms for various inputs

Linear search

• Let arr be an input array of length n. Given a value x, we want to find an index i (0 <= i < n), such that arr[i] == x. If no such index exists, then the algorithm returns -1.

Linear search

12	11	23	13	41	19	25
0	1	2	3	4	5	6

```
int lsearch(int arr[], int len, int val);   
What is the output of lsearch(arr, 7, 13)? Ans = 3 What is the output of lsearch(arr, 7, 30)? Ans = -1
```

Iterative linear search

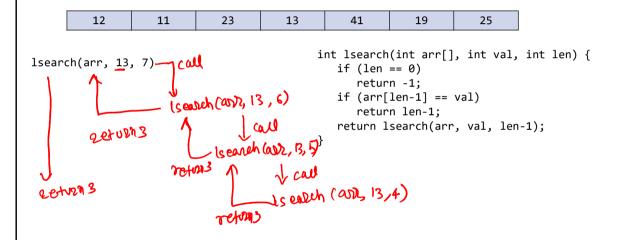

```
int lsearch(int arr[], int val, int len) {
   int i;
   for (i = len-1; i >= 0; i--) {
      if (arr[i] == val)
         return i;
   }
   return -1;
}
```

This linear search algorithm iterates all the elements in the array, starting from the last index to the start index. If the value of an array element is equals to val, it returns the corresponding index; otherwise, if val is not present in the array, Isearch returns - 1.

- •int lsearch(int arr[], int val, int len);
 - Initially, len is the length of the input arr
 - val is the value being searched

- int lsearch(int arr[], int val, int len);
 - Initially, 1en is the length of the input arr
 - val is the value being searched
- Base cases
- if (len == 0) return -1
 - if (arr[len-1] == val) return len-1
- Recursive step
 - Decrement the length of the array and recursively call search

```
int lsearch(int arr[], int val, int len) {
   if (len == 0)
      return -1;
   if (arr[len-1] == val)
      return len-1;
   return lsearch(arr, val, len-1);
}
```

                                                                       25
                                                  41
                                             int lsearch(int arr[], int val, int len) {
lsearch(arr, 13, 7)
                                                if (len == 0)
           calls
                                                   return -1;
                                                if (arr[len-1] == val)
                                                   return len-1;
         lsearch(arr, 13, 6)
                                                return lsearch(arr, val, len-1);
                       calls
                      lsearch(arr, 13, 5)
```

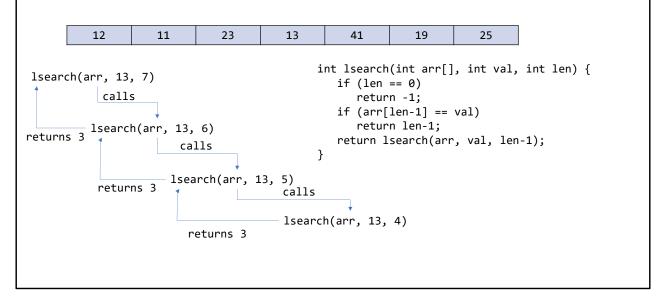

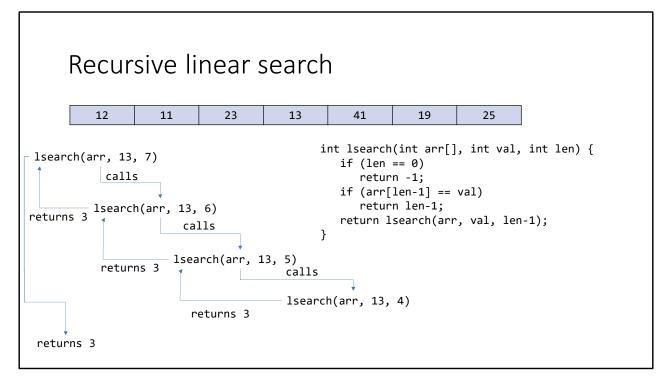

Isearch(arr, 13, 4) returns 3 because arr[len-1], i.e., arr[3] is equal to the value we are searching for, i.e., 13.

Isearch(arr, 13, 5) returns the return value of Isearch(arr, 13, 4), which is 3.

Isearch(arr, 13, 6) returns the return value of Isearch(arr, 13, 5), which is 3.

Isearch(arr, 13, 7) returns the return value of Isearch(arr, 13, 6), which is 3.

Let arr be an input sorted array (in ascending order) of length n.
 Given a value x, we want to find an index i (0 <= i < n), such that arr[i] == x. If no such index exists, then the algorithm returns -1.

int bsearch(int arr[], int len, int val);
search 15

The binary search algorithm works on a sorted array. The algorithm first computes the middle index (mid), which is equal to (start+end)/2, where start and end are the first and last index of the array. In this case, initially, mid is 5. If the val == arr[mid], then the algorithm simply returns mid; otherwise, if val > arr[mid], then the searching is performed in the subarray starting from mid+1 to end, else we search the element in the subarray starting from start to mid-1. If the element is not present in the array, the start index will eventually become lesser than the end index, and in that case, the algorithm returns -1.

11	15	19	23	41	59	65	75	79	81	87

search 74

Searching 74 in the range (0,10). mid = (0+10)/2 = 5. 74 > arr[5], search in the range (6, 10).

int bsearch(int arr[], int len, int val);
search 74

Searching 74 in the range (6,10). mid = (6+10)/2 = 8. 74 < arr[8], search in the range (6,7).

int bsearch(int arr[], int len, int val);
search 74

Searching 74 in the range (6,7). mid = (6+7)/2 = 6. 74 > arr[6], search in the range (7,7).

int bsearch(int arr[], int len, int val);
search 74

Searching 74 in the range (7,7). mid = (7+7)/2 = 7. 74 < arr[7], search in the range (7,6).

int bsearch(int arr[], int len, int val);
search 74

Searching 74 in the range (7,6). start > end. The value is not present. Returns -1.

Recursive solution

- int bsearch(int arr[], int val, int lo, int hi);
 - Initially, lo = 0 and hi = length(arr) 1
 - val is the value being searched
- Base cases
 - if (lo > hi) return -1
 - mid = (lo + hi)/2
 - if (arr[mid] == val) return mid
- Recursive step
 - If val > arr[mid], search the second half (mid+1, lo), recursively
 - Otherwise, search the first half (lo, mid-1)

Recursive solution

```
int bsearch(int arr[], int val, int lo, int hi) {
   if (hi < lo)
      return -1;
   int mid = (lo + hi) / 2;
   if (arr[mid] == val)
      return mid;
   if (arr[mid] > val)
      return bsearch(arr, val, lo, mid-1);
   else
      return bsearch(arr, val, mid+1, hi);
}
```
